

The possibilities are endless: Making sense of Local Energy System Modelling

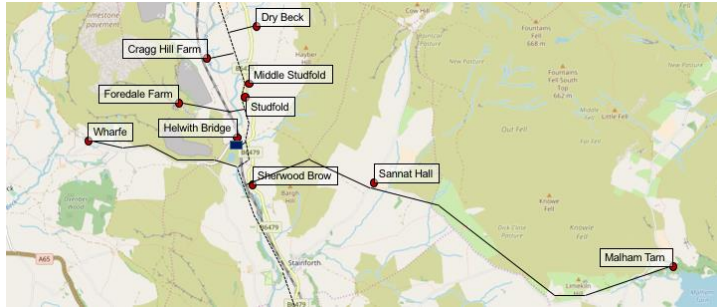

Graeme Hawker, Jack Flower and Keith Bell
Institute for Energy and Environment, University of
Strathclyde

Examining future local archetypes

Rural

Disaggregate UK energy system into exemplar archetypes

Urban

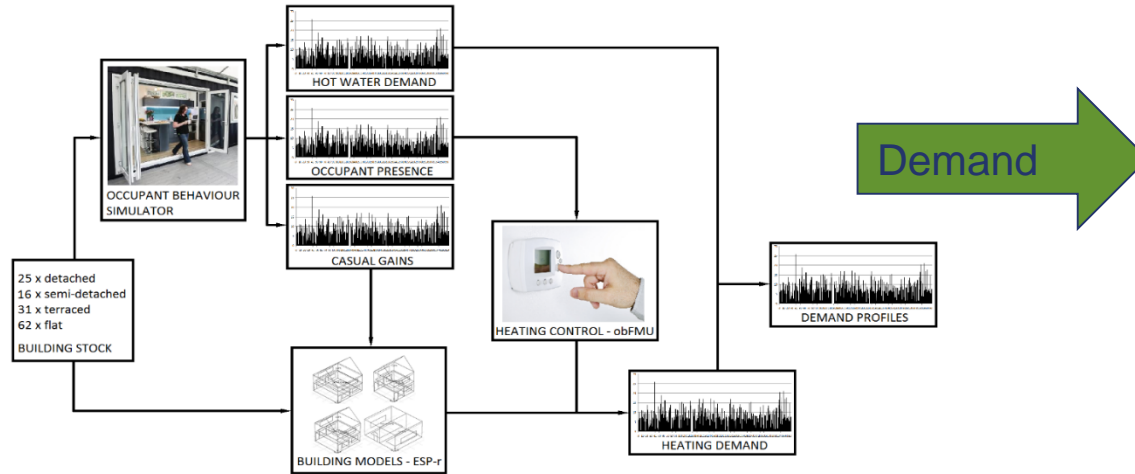

Modelling conducted within UKERC
Theme 3: **“Energy Systems at Multiple Scales”**

Sub-theme: **“Modelling spatial and temporal diversity”**

Suburban

Demand and technology modelling

Supply

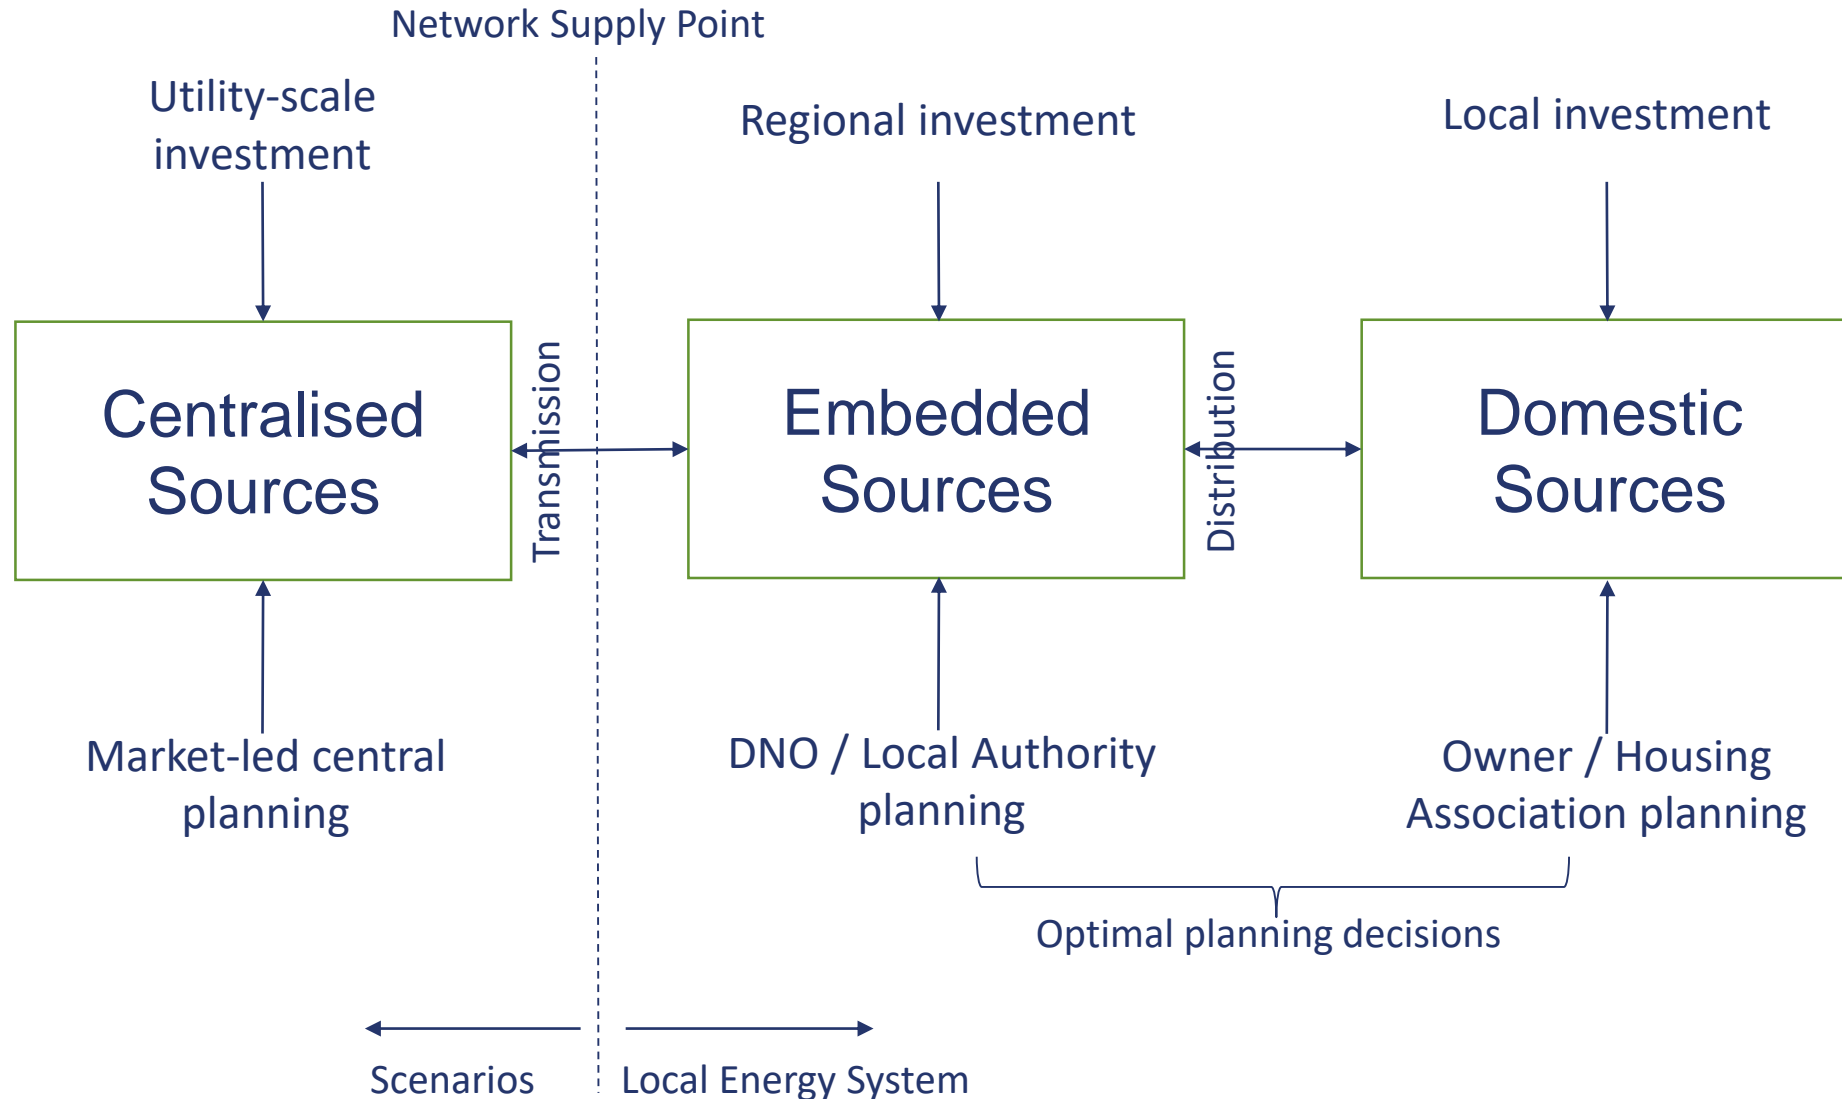

Evidence for costs and abatement

The end goal

- Achievable policies and business models which incrementally decarbonise real-world systems at a local scale
- For residential heating:
 - The ability to discern between ‘bridging’ solutions and long-term sustainable options
 - A clear picture of the likely technical performance and efficiency of low-carbon options
 - A breakdown of discrete responsibilities between homeowners/housing associations, local authorities, network owners/operators and national bodies
- A clear route to the ‘first million’ homes with low-carbon heating
 - Least regret? Whose regret?

Delineating the local system

Local issues in implementation

- “Technology isn’t the issue – we all know what to do”
- Project ownership
 - Cost of capital, risk allocation, control of assets
 - Public vs private infrastructure – continuum of ownership
- Persuasion and authority
 - Need for anchor customers?
- Uncertain evolution of regional/national-scale systems
- Danger of near-term small-scale efforts undermining the business case for more transformative change

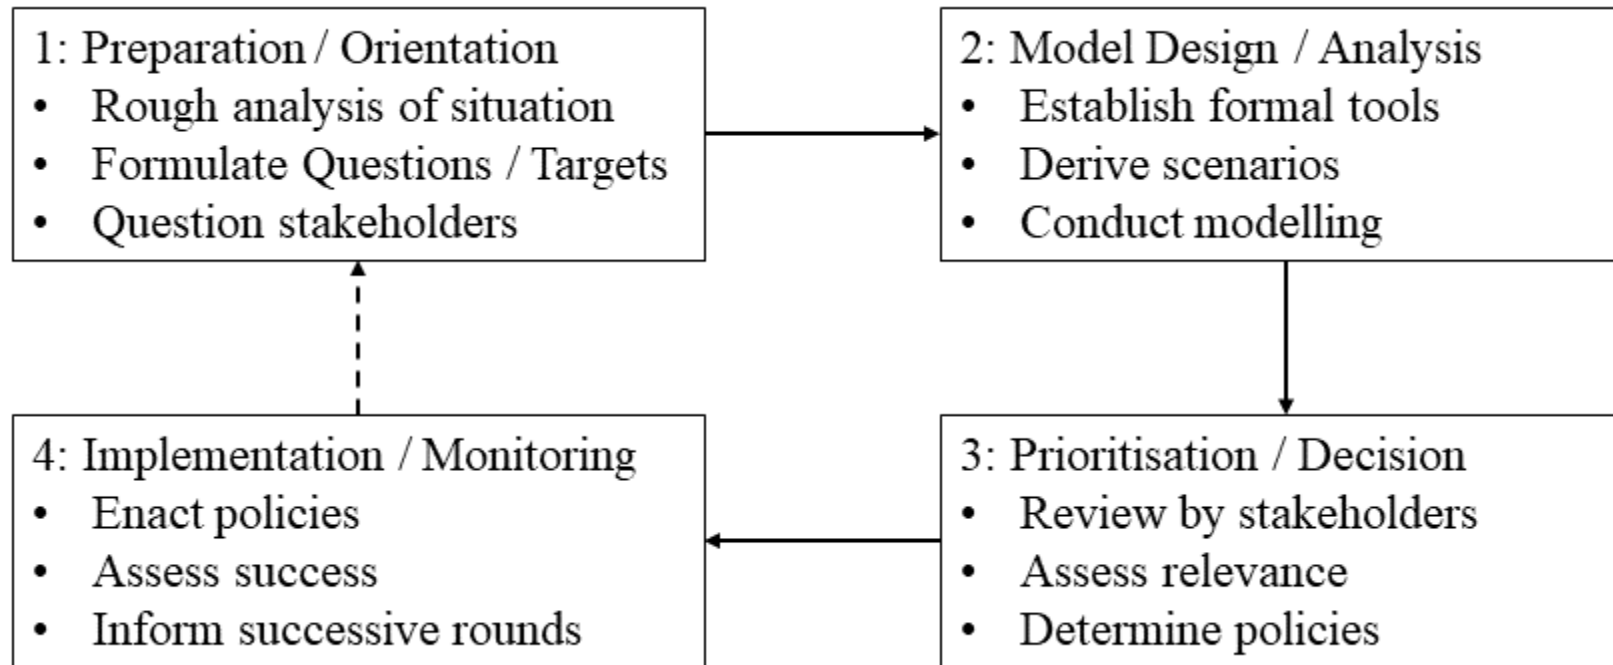

Optimality?

- The failure of techno-economic models to represent non-technical or economic constraints on technology investments may lead to a recommended trajectory which is not feasible when behavioural and political requirements are considered
- Political will and public acceptance are also limited resources alongside cost
- Least-cost minimisation is perhaps justified only where an overarching economic driver exists or there is an actor who has the global purview to enact policies across that domain

What makes a model 'useful' to a local actor?

- **Conceptualisation:** Demonstrating (qualitatively or quantitatively) a previously unknown contribution
- **Quantification:** Confirming a hypothesised contribution by a technology, policy or implementation
- **Comparison:** Comparing and/or contrasting different technology/policy/implementation options
- **Contextualisation:** Adding additional detail to previous analyses on how such technologies/policies might be implemented and how they may interact with complex extant systems
- **Certainty:** Reducing the uncertainty (and by extension the risk) associated with one of the above
- **Application:** Illustrating some aspect of the above within a specific real-world context

Stakeholders in model design

J. Flower, G. Hawker, K. Bell, (2019) *Heterogeneity of UK Residential Heat Demand and its Impact on the Value Case for Heat Pumps*

Non-incremental change

- All trajectories to decarbonisation involve non-incremental change for some actor at some level, e.g.
 - Domestic consumers investing in a change of heating technology
 - CHP and district heating systems requiring critical volume of buy-in
 - Increasing electrical demand requiring infrastructure reinforcement both locally and at higher voltages
 - Natural gas to hydrogen conversion requiring regional switch-over and potential huge costs for transmission
- Local systems have dependencies and impacts on regional and national systems
- The means and responsibilities for coordinating non-incremental change among actors (both local and supply-side) is not clear

The contribution of local diversity

GHG90 alternative cases

Residential sector emissions

Steps taken to accelerate deployment of unconventional systems lead to their increased contribution to emissions reduction over heat pumps – a role for more varied incentives?
